

Slicing - Using slicing we can access substring (part of string)

Print (str1[4]) → 'g'

Print (str1[-6]) → 'g'

Slicing Syntax:

String_name [Start : Stop : Step] (by default 0)

Start : index, our slicing starts.

Stop : index, our slicing stops. (by default len(str))
we consider (stop index + 1)

Step : interval between characters (by default 1)

str1 [0 : 3] → 'jai'

String Properties :-

1. Immutability — Can't modify/change.

once we defined the string, we can't modify/change it.

Str1 = "jañganes
matu di"

→ Error

2. Concatenation - Using + operator, we can combine two different strings, or more than that

Str1 = "jai"

Str2 = "ganesha"

Str3 = Str1 + Str2

Print (Str3) → "jaiganesha"

3. Repetition - Using * operator
we can repeat string multiple
times.

eg. str1 = "jai ganesh"

str2 = "jai ganesh jai ganesh ---
-----"

str3 = str1 * 100

4. Indexing - Already discussed

5. Slicing - Already discussed.

6. Membership testing - we use
'in' operator to check whether
particular substring is available in
the string or not.

Q. str1 = "jai ganesh"

print("jai" in str1) → True

print("hello" in str1) → False

Built in functions :

1. `len()` :- Using `len()` function we print the length of the string.

ex. `str1 = "jai ganesha"`

`print(len(str1))` $\rightarrow$ 10

2. min() -

eg. str1 = "jai ganesh"
print(min(str1)) →
