

Python Basic Data Types

- 1) integer
- 2) float
 - Decimal
 - exponential
- 3) Complex - real + imaginary
 - Decimal
 - binary
 - Octal
 - hexadecimal
- 4) bool - True or False.
- 5) String

• What are strings ?
→ String is collection of unicode characters.

Unicode character — capital alphabets (A-Z)
small alphabets (a-z)
digits (0-9)
special char
(@, \$, % - -)

String is written inside single,
double or tripple quotes (inverted
comma)

eg. 'jai Ganesh' — single quotes

"jai Ganesh" — double quotes

'''jai Ganesh''' — tripple quotes

To access the entire String or to display the entire string, we use that variable to display it.

```
Str1 = "jai ganesh"
```

```
Print(Str1)
```

```
o/p - jai ganesh
```

Indexing - Using indexing, we can access/display the individual element of the string.

- String is sequence of characters.
- every character/element has position, called as index

There are two types of indexing

1) Positive indexing — Starts from
0 (first char.)

2) Negative indexing — Starts from
-1 (last char.)

the indexing	0	1	2	3	4	5	6	7	8	9
str1	j	a	i		g	a	n	e	s	h
-ve indexing	-10	-9	-8	-7	-6	-5	-4	-3	-2	-1

str1 = "jai ganes h"

Print (str1) → jai ganes h

Print (str1[4]) → g

Print (str1[-6]) → g

str1 = [j | a | i | g | a | n | e | s | h]

True
index 0 1 2 3 4 5 6 7 8 9

→

print(str1[0]) → j print(str1[5]) → a
print(str1[1]) → a print(str1[6]) → n
print(str1[2]) → i print(str1[7]) → e
print(str1[3]) → g print(str1[8]) → s
print(str1[4]) → g print(str1[9]) → h

str1 = [j | a | i | | g | a | n | e | s | h]

-10	-9	-8	-7	-6	-5	-4	-3	-2	-1
-----	----	----	----	----	----	----	----	----	----

print(str1[-10]) → j

print(str1[-9]) → a

print(str1[-8]) → i

print(str1[-7]) →

print(str1[-6]) → g

print(str1[-5]) → a

print(str1[-4]) → n

print(str1[-3]) → e

print(str1[-2]) → s

print(str1[-1]) → h
